No. is the number of results predicted by chance to have a score greater than or equal to the score of the result being printed, and is derived by analysis of the total score distribution.
                                                                                                                                                               Description

Transforming plants with a nucleic acid molecule encoding cytochrome P450 reductase alters the yield and/or type of alkaloids produced.

To optum poppies it specifically increases the yield of medically useful alkaloids such as morphine, codeine, oripavine and thebaine. Sequences complementary to the coding sequence of cytochrome P450.

Ceductase are useful as probes, primers and antisense sequences, or for design of ribozymes. Transformation with DNA encoding the content and of the relative proportions of individual alkaloid content and of the relative proportions of individual alkaloids. Content and of the relative proportions of individual alkaloids.

Transformed the cost of alkaloid production. Cytochrome P450 reductase is the rate-limiting enzyme in biosynthesis of alkaloids in poppies. Peptide fragments of the cytochrome P450 reductase are described in ANWBS672-W85678. poppy from other; P-450 reductase T; 0 764 606 G; encoding cytochrome : : English 514 AAW85682 Ä; 58pp; 991 BP; AAW85680, 9a; 2650 acid Fig Sequence PSDB; Nucleic Claim

                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 ttttttggtactcagactggtactgctgaaggatttgctaaggcattggcagaagaaatt 429
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             cytochrome P450 reductase involves transforming yeasts with plasmids of a total CDNA bank of plant(s). The yeasts used in the procedure are incapable of producing their own NADPH cytochrome P450 reductase. They are then exposed to a cytochrome P450 inhibitor at a level which is lethal to the yeast cells but not to cells which, because of the transformation, now contain an active NADPH cytochrome P450 reductase. Surviving clones are then isolated and
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          Gaps

P450 reductase alters the yield and/or type of alkaloids produced. In opium poppies it specifically increases the yield of medically useful alkaloids such as morphine, codelne, oripavine and thebaine. Sequences complementary to the coding sequence of cytochrome P450 reductase are useful as probes, primers and antisense sequences, or for design of ribozymes. Transformation with DNA encoding the

```

A new method for determining whether a DNA sequence encodes an NADPH cytochrome P450 reductase involves transforming yeasts with plasmids of a total cDNA bank of plant(s). The yeasts used in the procedure are incapable of producing their own NADPH cytochrome P450 reductase. They are then exposed to a cytochrome P450 inhibitor at a level which is lethal to the yeast cells but not to cells which, because of the transformation, now contain an active NADPH cytochrome P450 reductase. Surviving clones are then isolated and plasmid DNA extracted. The gene is inserted into the plasmid at a site which places it under the control of an inducible promoter. New DNA encoding plant NADPH cytochrome P450 reductase - cloned by functional complementation in yeast, also recombinant enzyme useful in P450 mediated bioconversion processes Sequence 2423 BP; 674 A; 497 C; 552 G; 700 T; 0 other; Minet M; /*tag= ad /transl_except= CGA encodes Lys. 2027..2029 Lys. /*tag- y //trag- y //trag- y //trags_except- AGA encodes Lys.misc_difference 1877..1879 /*tag= aa /transl_except= AGA encodés Lys. misc_difference 1943..1945 /*tag= ac

The yeasts used in the procedure are incapable of producing their own NADPH cytochrome P450 reductase. They are then exposed to a cytochrome P450 inhibitor at a level which is lethal to the yeast cells but not to cells which, because of the transformation, now contain an active NADPH cytochrome P450 reductase. Surviving clones are then isolated and plasmid DNA extracted. The gene is inserted into the plasmid at a site which places it under the control of an inducible promoter.
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              Gaps

                                                                                                                                                                                                                                                                                                                                                                                                                                                  The sequence may be used to construct a plasmid which may transform a yeast expression system to produce both rat hepatocytcochrome P-450MC and NADPH cytochrome P-450 reductase (Fpt). This is useful in removal of organic compounds from toxic waste water. The yeast is capable of hydroxidising the P-position of acctanilide useful in the production of acctanilide useful in the production of actaminophenes which are antipyuretics and analgesics.
                                                                                                                                                                                                                                                                                                                                                                                     Plasmid p-ARM1 simultaneously expressing rat hepato-cytochrome P-450MC - and NADPH-cytochrome P-450 reductase in yeast and yeast
